# An Automatic Contrast Validation Approach for Smartphone Themes

Aasim Khurshid  
Adriano Gil  
Felipe Guimarães  
Mikhail R. Gadelha  
Everlandio Fernandes

# Smartphone Themes

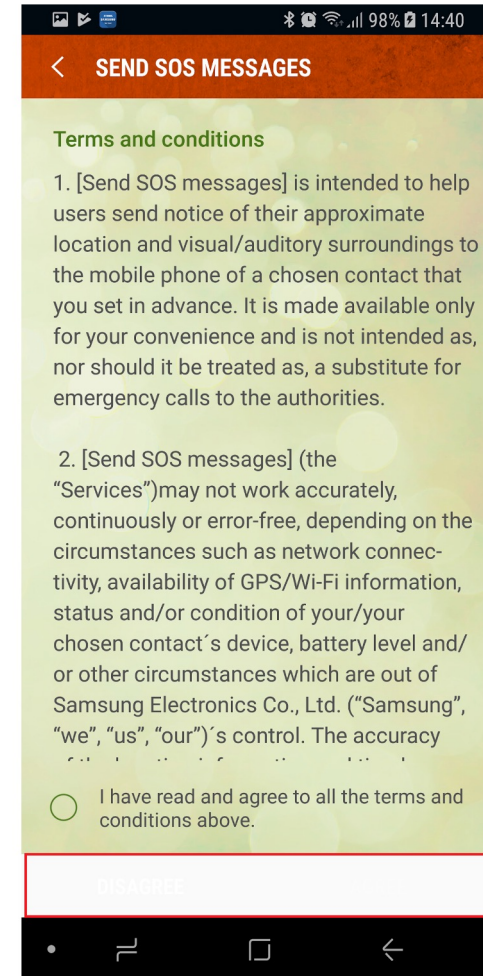

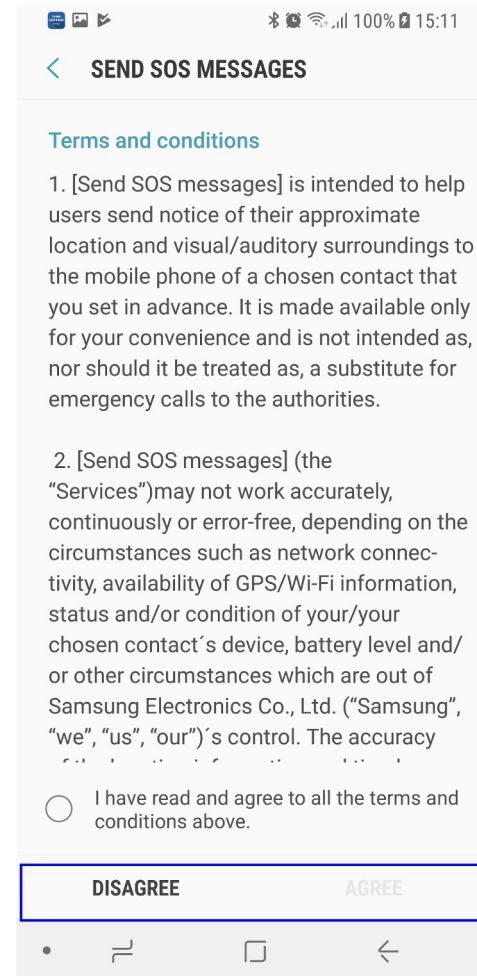

- Customizes more than 100 screens of Android OS UI
- Theme development is an error-prone process that involves configuring more than 200 parameters
- Sometimes a minor change on parameters can generate a visual issue that is hardly detected

# Main Challenges

- How to validate the contrast between UI elements?
- The contrast can be described as
  - High Perceivable Contrast (HPC)
  - Low Perceivable Contrast (LPC)

Contrast issues reported by Galaxy Theme Store

Due to a wrong text color, text is not visible on bottom buttons

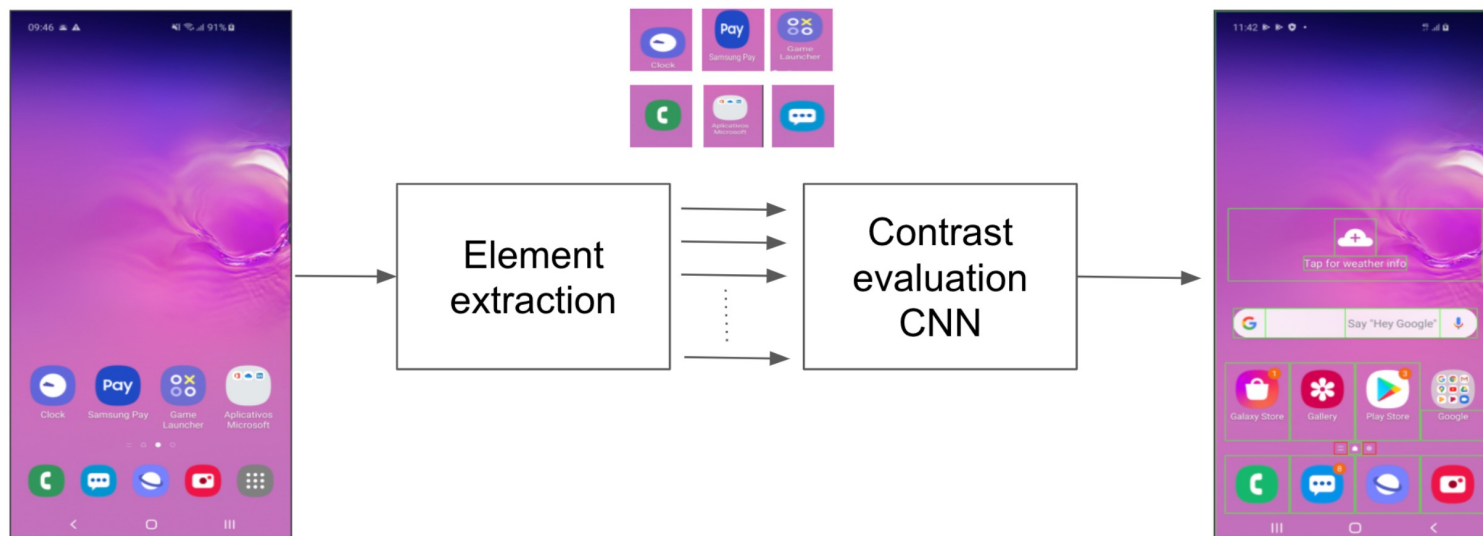

# Proposed Approach

- In this work, we propose an automatic themes evaluation approach that validates the contrast of Android smartphone themes among regular (HPC) and non-regular (LPC) at the element level.

# Proposed Approach

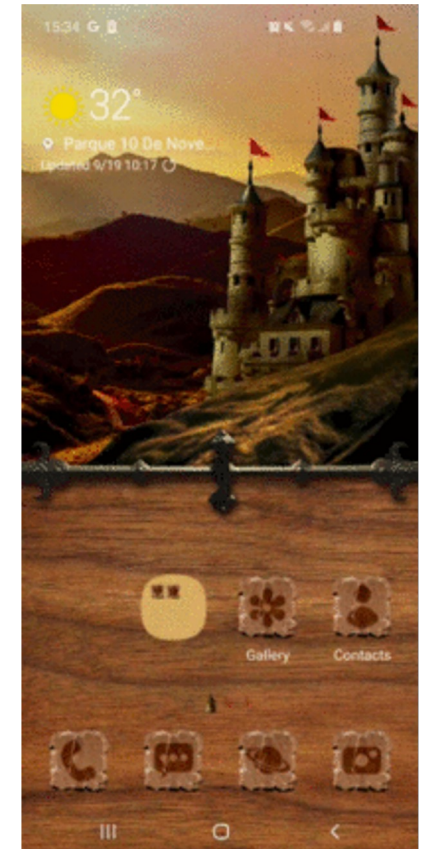

- To address this challenge, our solution is divided into two phases:
  - **Element extraction:** a mobile application for Android that walks into several screens, takes screenshots and extracts UI information
  - **Contrast Evaluation:** a python-based desktop application that analyzes screenshots and generates a detailed report of any low contrast issues it found.

# Proposed Approach

# Elements Extraction

- We implemented an Android solution built on top of:
  - UIAutomator: used to simulate inputs
  - Accessibility service: used to extract UI information
- The algorithms in the desktop module **extract the elements** from the screenshot and **send them to our contrast evaluation algorithm**

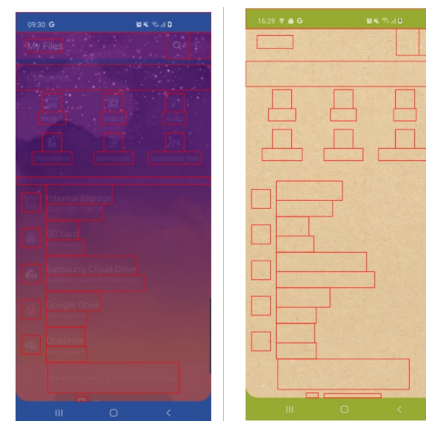

# Contrast Evaluation

- Everlandio et al [6] uses a Faster RCNN with an average precision of 79.91%
- Our approach is based on **Convolutional Neural Network (CNN)**
- **Segmented UI elements** are used as input for our CNN that classifies between two labels:
  - High Perceivable Contrast (HPC)
  - Low Perceivable Contrast (LPC)

# Dataset

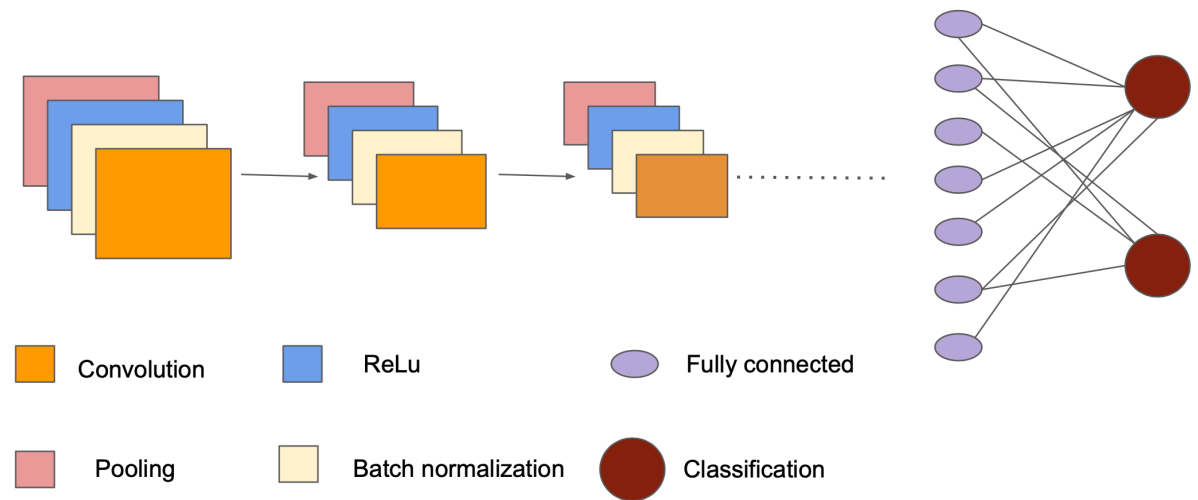

- We created **200 themes** with a wide range of low contrast issues
- For each theme, we captured **122 screenshots**
- **56070 elements** were extracted and manually labeled
- We defined datasets for dark- and light-color themes

| Dataset    | Dark  | Light | Total |
|------------|-------|-------|-------|
| Training   | 29390 | 26680 | 56070 |
| Validation | 14658 | 13360 | 28018 |
| Test       | 4520  | 4296  | 8816  |

# Neural Network Architecture

- Our **Convolutional Neural Network** has only **5 layers**
- In the final part of model architecture there is a fully connected layer followed by a softmax for classification between two labels (LPC and HPC)

# Results

- The proposed contrast evaluation network is compared quantitatively with the ResNet50 [17], AlexNet [18] and GoogleNet [19] representative of the state-of-the-art for classification, using the following measures:
  - Attack Presentation Classification Error Rate (APCER)
  - Normal Presentation Classification Error Rate (NPCER)
  - Average Classification Error Rate (ACER)
  - False Positive Rate (FPR)
  - True Positive Rate (TPR)
  - True Negative Rate (TNR)
  - Accuracy
  - F1 score
  - processing time

# Results

| Method   | APCER         | NPCER         | ACER          | FPR           | TPR           | TNR           | Accuracy      | F1 Score      | Processing time (seconds) |
|--|---------------|---------------|---------------|---------------|---------------|---------------|---------------|---------------|---------------------------|
| Training and test data extracted from Lightset dataset |               |               |               |               |               |               |               |               |                           |

| <b>Proposed CNN</b>                                    | 0.0817        | 0.0444        | <b>0.0631</b> | 0.0817        | 0.9556        | <b>0.9183</b> | <b>0.9354</b> | <b>0.9314</b> | <b>49.08</b>              |

# Results

- The proposed method has performed consistently well for both the datasets and only has a difference of 0.3 points across datasets.
- Furthermore, the proposed method outperforms all the other methods on the Darkset and is second on the lightset in terms of accuracy and F1 score to GoogleNet [19]

# Conclusion

- We presented a solution that traverses Android GUI, automatically takes screenshot and UI information of 122 screens and check for low-contrast issues
- Using a Convolutional Neural Network we achieved a high F1 score and fast processing time
- We concluded that a network architecture with a small number of layers is more able to classify among elements containing or not containing contrast issues.
- In future works we plan to tackle dark and light—colored themes using a single model
